

Right to Left PDA

Example of CW-Doppler in the Right to Left PDA, indicating that the PA pressure is 46 mmHg above the Ao pressure at peak of systole (3.4 m/s). Because of its restriction, there is significant pressure build up within the duct with some flow in diastole. The velocity of flow gets close to baseline before the end of the cardiac cycle, possibly because PA pressures are getting closer to diastolic pressure at that timepoint, or the duct lumen is closing towards end of diastole (if it is quite small) not letting much pass through it before the next systolic phase.

PW-Doppler of right to left PDA (unrestrictive).
